# Cotlook A Index

## Aug 2009 – Nov 2012

A Index, US cents/lb

# Contents

- Definition
- Challenges in Measuring Volatility
- Methods and Estimates of Cotton Price Volatility
- Overview of Methods
- Caveats

# Price Volatility

Degree of dispersion/concentration of prices:

- High volatility: high dispersion (low concentration)
- Low volatility: low dispersion (high concentration)
- Volatility  $\neq$  Level of prices

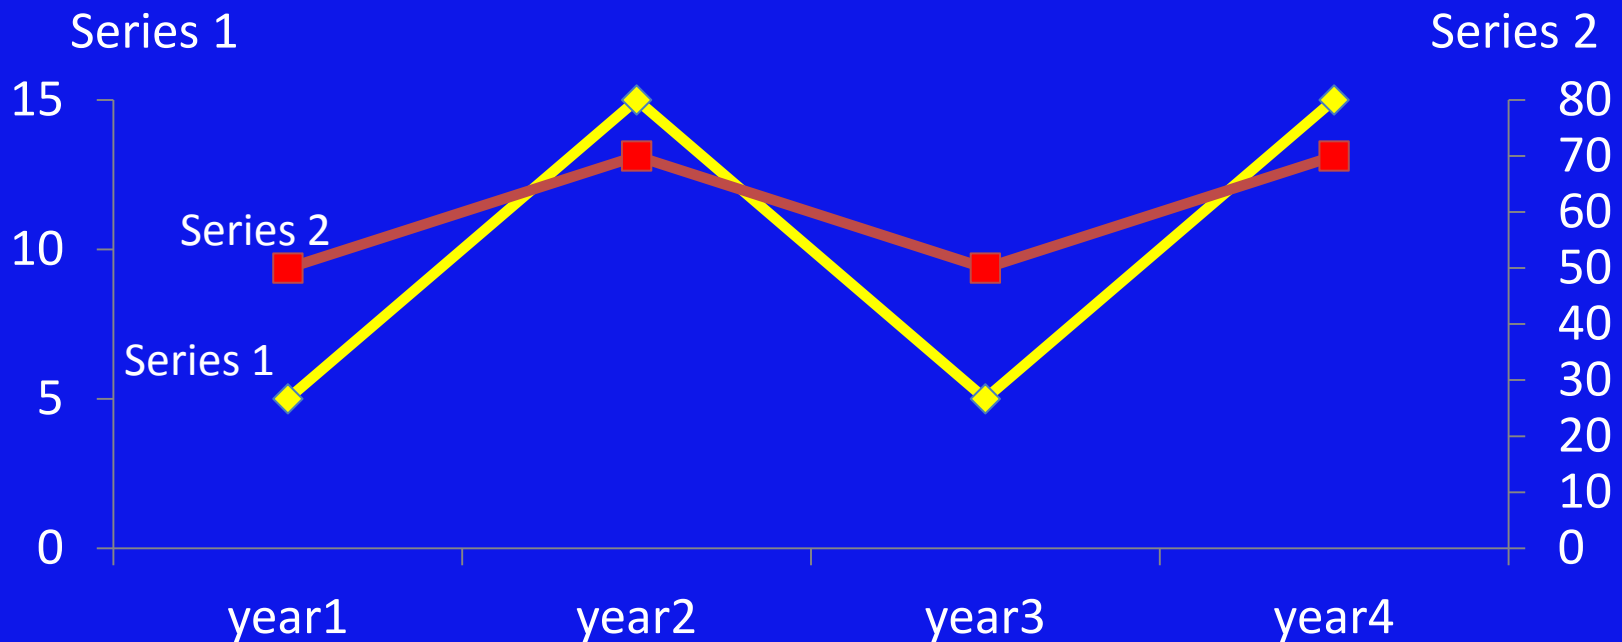

# Challenges in Measuring Volatility

- Scale effect
- Path dependency
- Trends
- Frequency of data

# Scale Effects

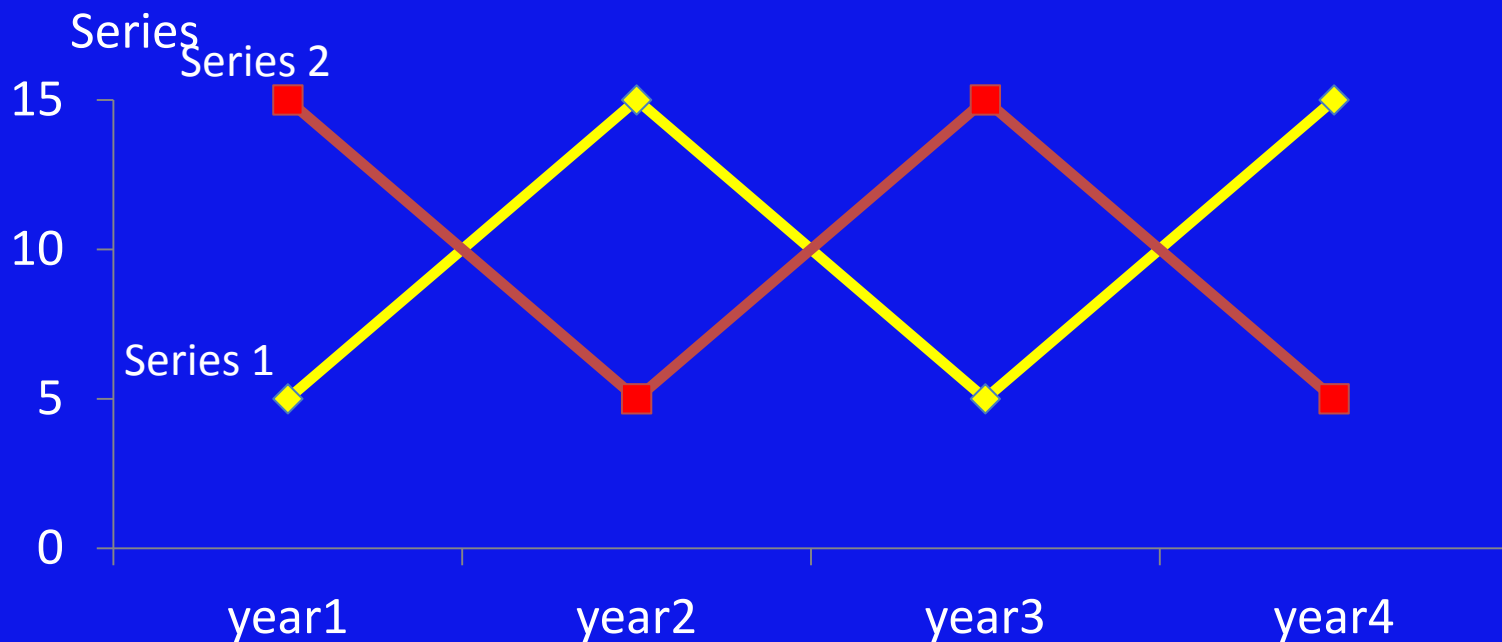

- Range = highest – lowest
- Range Series 1 = \$10
- Range Series 2 = \$20
- Which series is more volatile?

# Path Dependency

- Same Range
- Same Average
- Which series is more volatile?

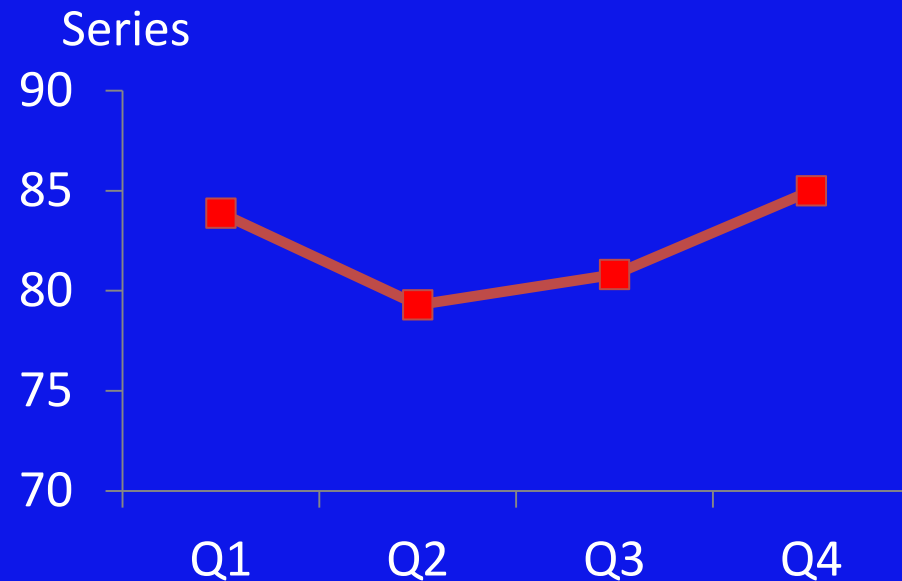

# Trends

- Same Range
- Same Average
- Series 1 has a trend
- Which series is more volatile?

# Data Frequency

- Data Aggregation (monthly, quarterly, etc.):
- Same Averages
- Lose information on distribution
- Which series is more volatile?

# Methods to Gauge Volatility

- 1) Relative Spread
- 2) Coefficient of Variation
- 3) Mean Absolute Percentage Forecast Error
- 4) Standard Deviation of Log Difference in Prices

# Relative Spread

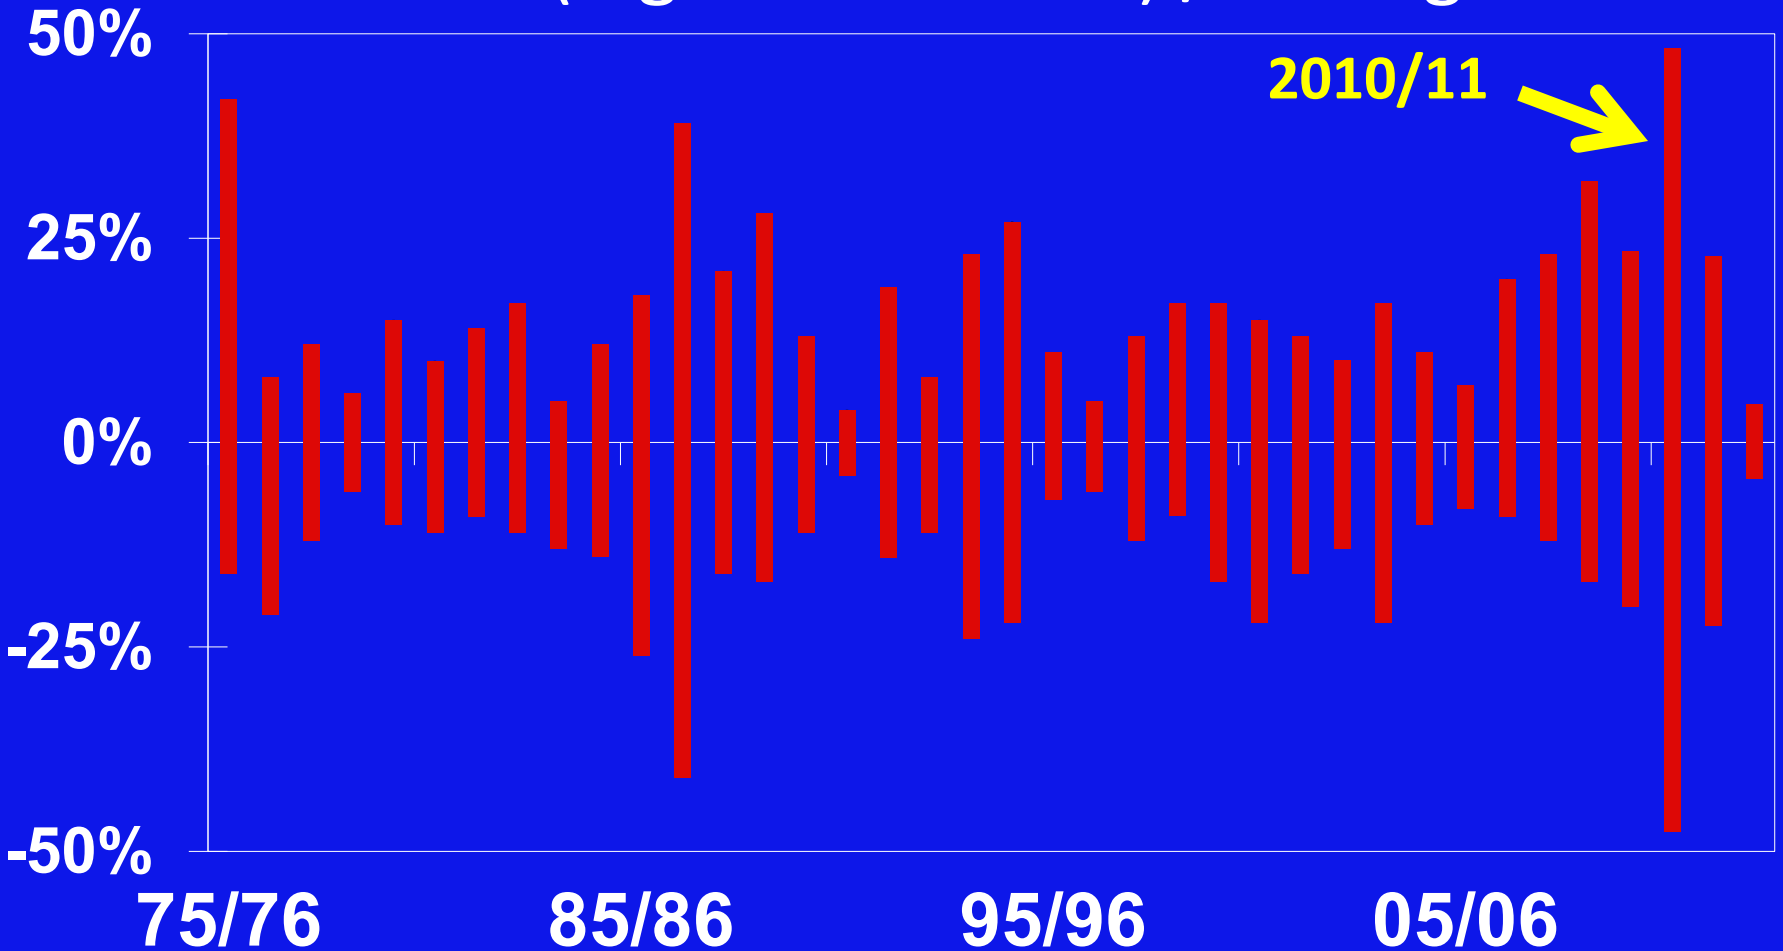

- $RS = (\text{highest} - \text{lowest}) / \text{average}$
- Advantages:
  - Easiest to communicate
  - No scale effect
  - Path neutral
- Disadvantages:
  - NO use of info on distribution of prices
  - Only extreme values and mean
  - Does not account for trends

# Relative Spread: A Index by Crop Year

## Daily Quotations

RS = (highest – lowest) / average

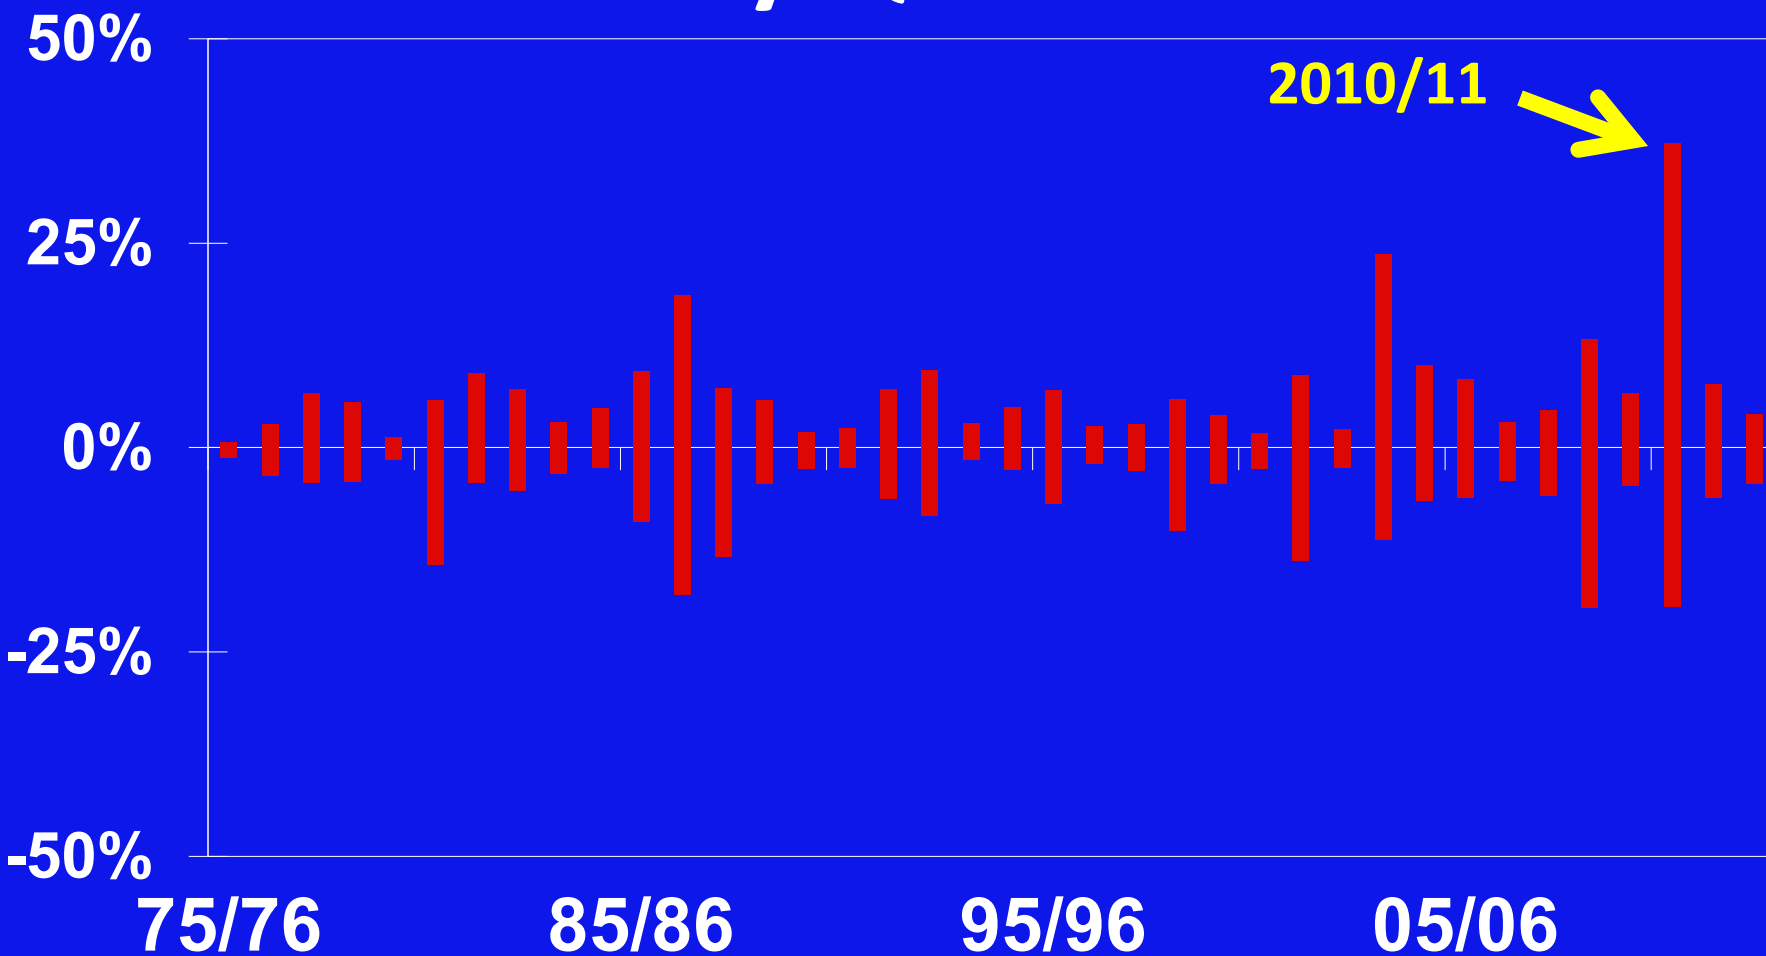

2010/11

2012/13: August – November

# Relative Spread: A Index, First 3 Months of Each Crop Year Daily Quotations

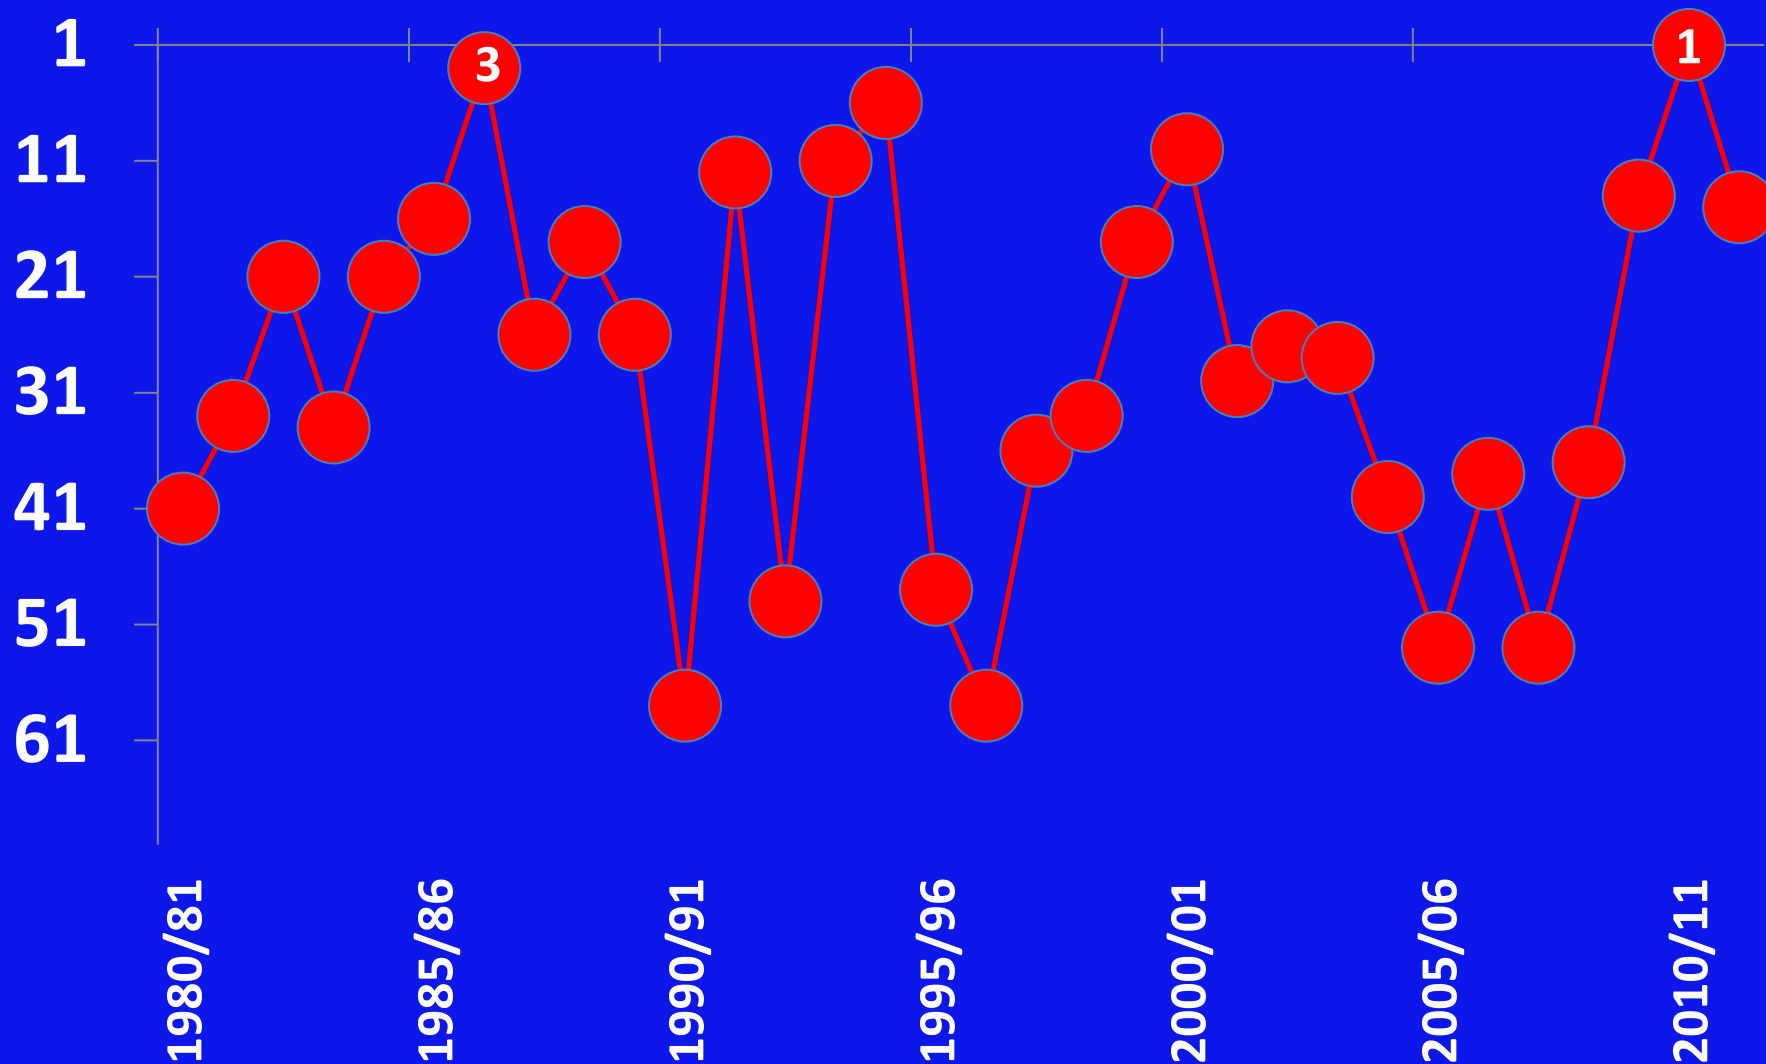

2010/11

2012/13: August – November

# Ranking of Cotton Price Volatility among 64 Commodity Prices (RS)

2011/12: August - December

# Coefficient of Variation

- $CV = \text{standard deviation} / \text{average}$
- Advantages:
  - Easy to communicate
  - No scale effect
  - Path neutral
  - Uses entire distribution of prices
- Disadvantages:
  - Does not account for trends

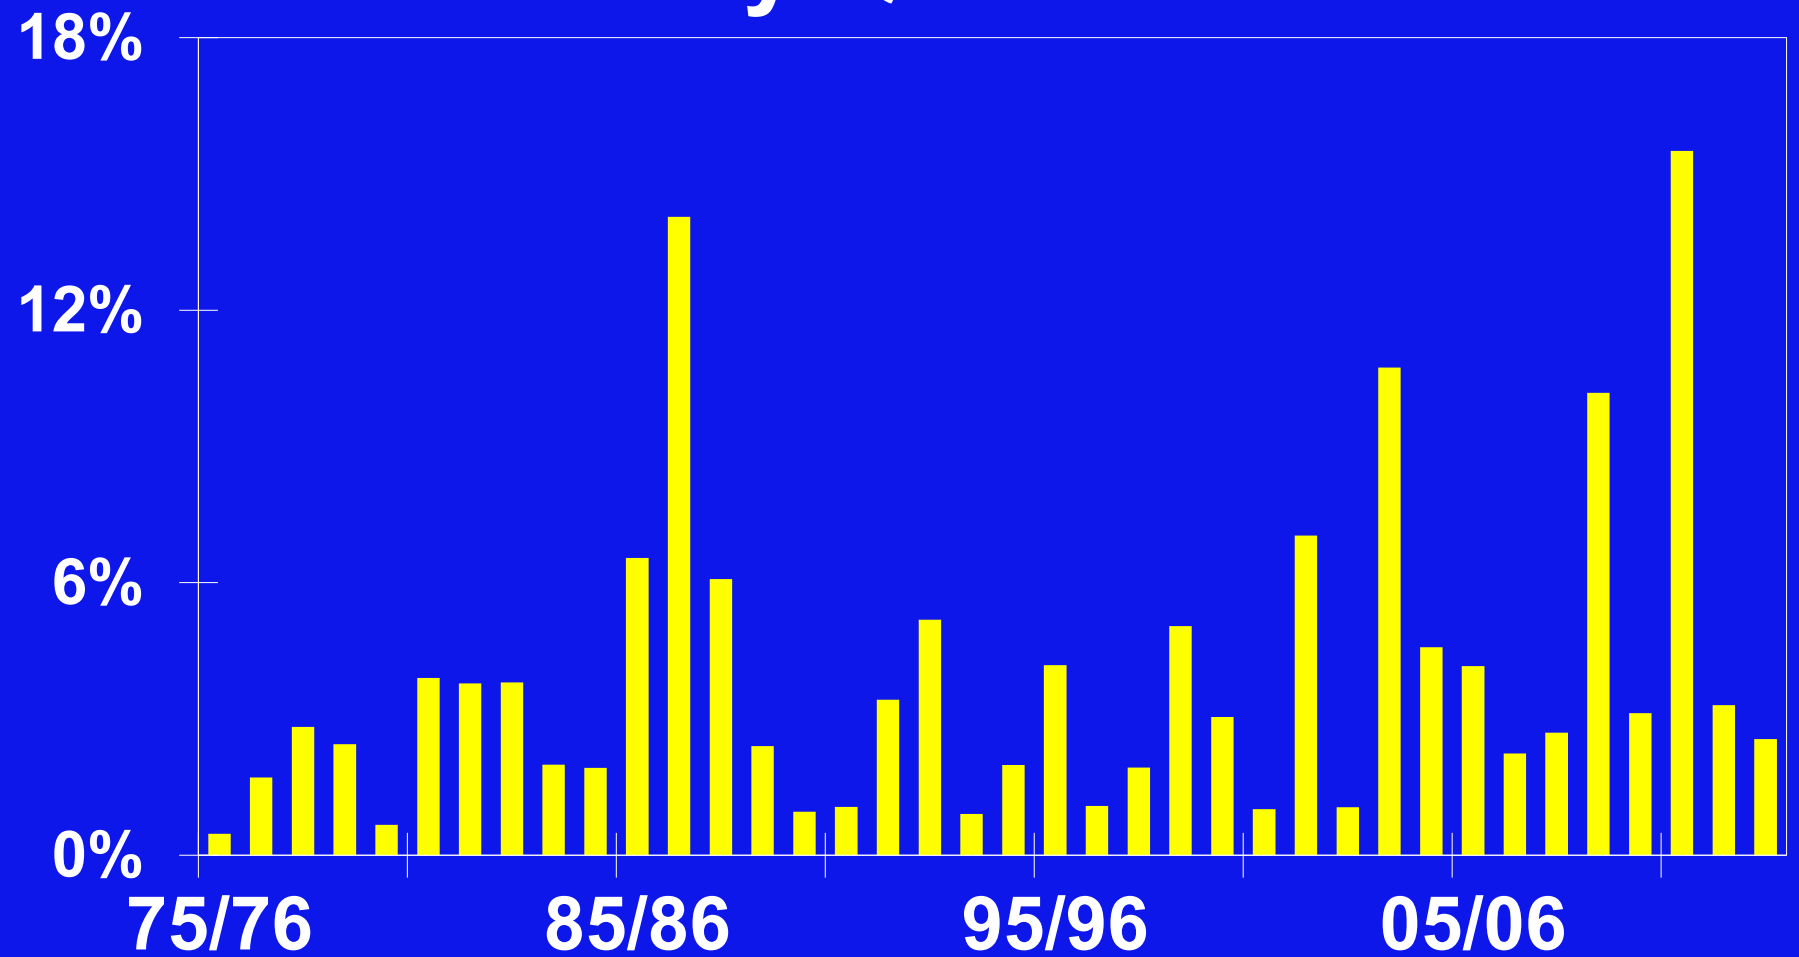

# Coefficient of Variation: A Index by Crop Year, Daily Quotations

2012/13: August – November

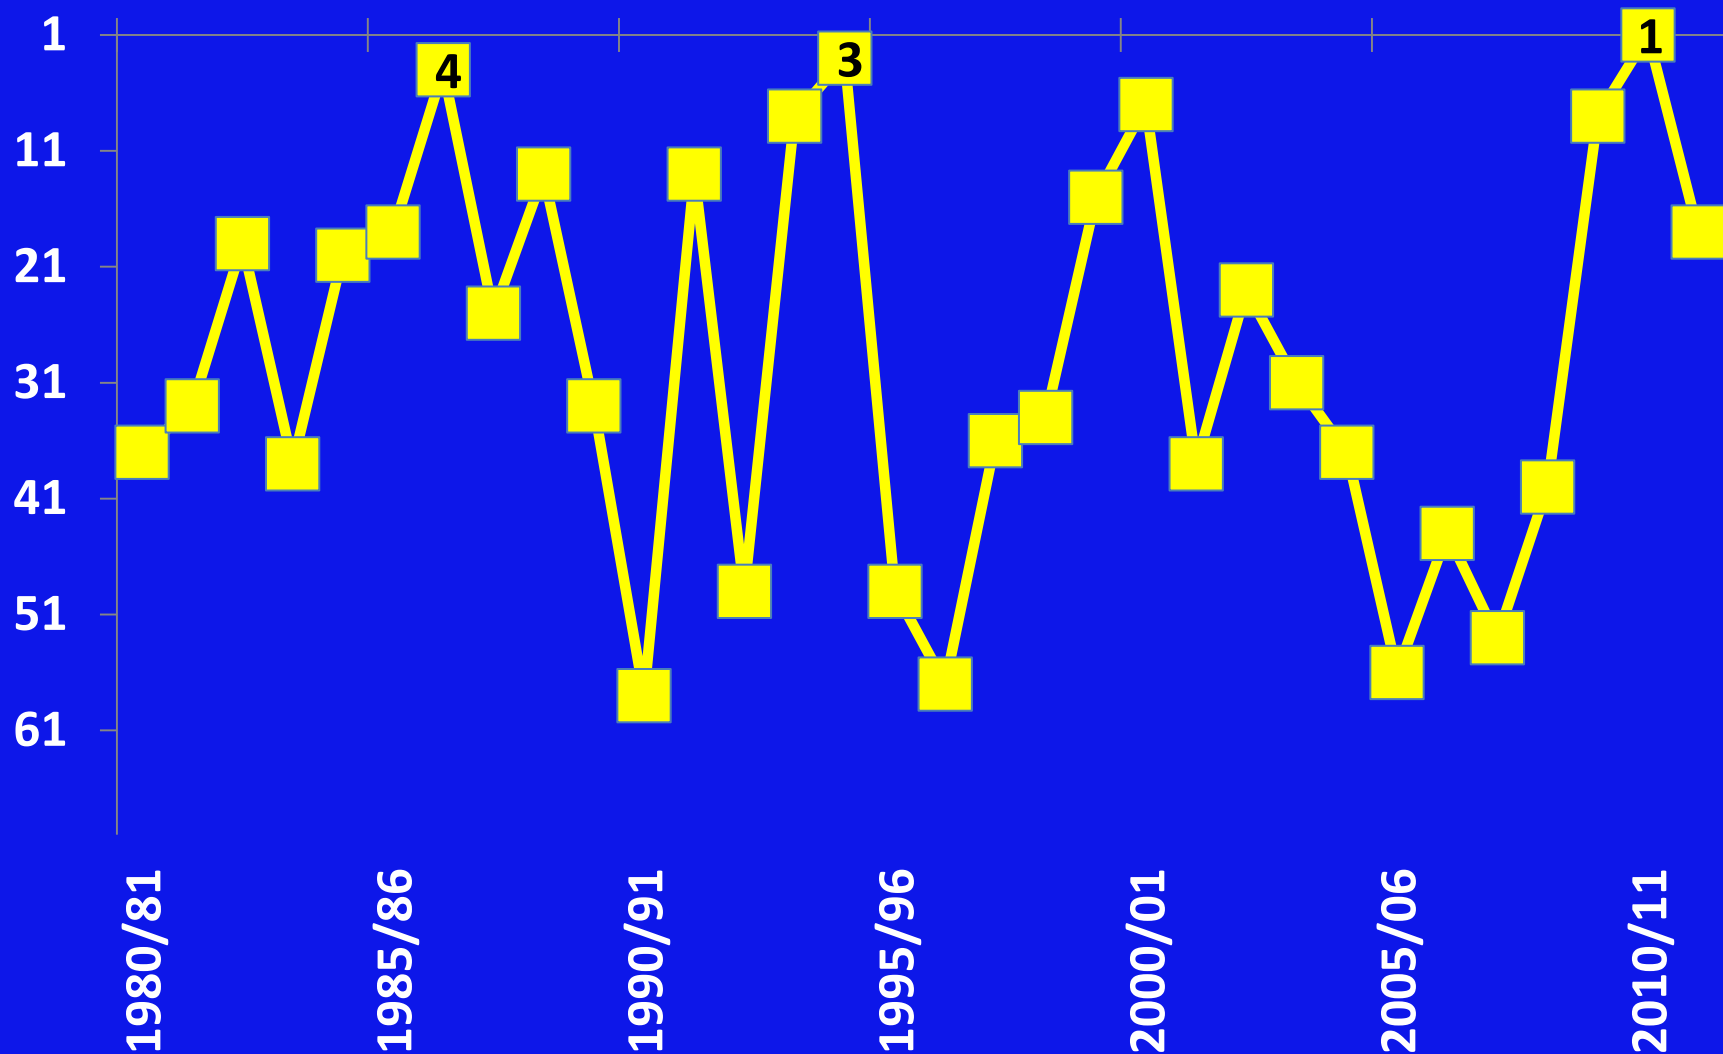

# Coefficient of Variation: A Index First 3 Months of Each Crop Year Daily Quotations

August - October

# Ranking of Cotton Price Volatility among 64 Commodity Prices (CV)

2011/12: August - December

# Average A Index vs. Volatility Measures by Seasons

## Relative Spread

## Coefficient of Variation

# Mean Absolute Percentage Forecast Error

- MAPFE = Mean absolute value of the % difference between the one step ahead forecast produced with a constant and a trend, and the observed price.

$$\sum_{t=1}^{T-1} |\hat{p}_{t+1} - p_{t+1}| / (T-1)$$

$$p_t = \alpha_0 + \beta \text{Trend}_t + \varepsilon_t$$

$$\overline{R^2} = \sum_{t=1}^{T-1} R_{t+1}^2 / (T-1)$$

# Mean Absolute Percentage Forecast Error

## Advantages:

- No scale effect
- Does account for trends
- Uses entire distribution of prices

## • Disadvantages:

- Not so easy to communicate
- Path dependent
- If Average  $R^2$  low, MAPFE not relevant

# Mean Absolute % Forecast Error: A Index by Crop Year

2012/13: 1 August – 17 Nov

# Mean Absolute % Forecast Error: A Index, First 3 Months of Season

# Mean Absolute % Forecast Error: A Index by Crop Year

2012/13: 1 August – 17 Nov

# Standard Deviation of the % Change in Prices: GARCH-M model

- General Autoregressive Conditional Heteroskedastic in mean model
- Model of inter-daily changes in prices:

$$d\log(A_t) = a_0 + \sum_{i=1}^3 a_i d\text{daym}_{it} + b_0 d\text{ICE}_t + \sum_{i=70s, \dots, 00s} b_i d\text{decade}_{it} + \sum_{i=1}^J d_i d\log(A_{t-i}) + gh_t + \varepsilon_{1t}$$

- Model of conditional variance of  $\varepsilon_{1t}$ :  $\varepsilon_{1t} = v_t \sqrt{h_t}$

$$h_t = \alpha_0 + \sum_{i=1}^q \alpha_i \varepsilon_{1t-i}^2 + \sum_{i=1}^p \beta_i h_{t-i} + \delta_0 d\text{ICE}_t + \sum_{i=80s, \dots, 00s} \delta_i d\text{decade}_{it} + \varepsilon_{2t}$$

# Standard Deviation of the % Change in Prices: GARCH-M model

- Advantages:
  - No scale effect
  - Uses entire distribution of prices
  - Accounts for trends
  - Clear hypothesis testing
  - Focused on confidence intervals of changes in prices
- Disadvantages:
  - Difficult to communicate
  - Path dependent

| Variable         | Coefficient | Std. Error | z-Statistic | Prob.  |
|------------------|-------------|------------|-------------|--------|

| $\delta_{90s} - \delta_{00s} = 0$ | 0.17        | 9345               | 0.869   |

# GARCH-M model: A Index Daily Quotations

- End of open outcry ICE did not significantly affect volatility
- Volatility increased every decade from the 1970s to the 1990s and it stabilized until 2010/11.
- Volatility in 2010/11 exceeded historical average.

# Methods to Gauge Volatility

|  | Scale Effect | Path Dependency | Accounts for Trends              |
|--|--------------|-----------------|----------------------------------|
| Relative Spread                                | No           | Neutral         | No                               |
| Coefficient of Variation                       | No           | Neutral         | No                               |
| MAPFE: Mean Absolute Percentage Forecast Error | No           | Dependent       | Yes: short-term trends           |
| StdDev %Change in Prices: GARCH-M model        | No           | Dependent       | Yes: long- and short-term trends |

# Concluding Remarks

- Volatility depends on:
  - Frequency of data
  - Measurement method
  - Period over which it is measured
- All methods: 2010/11 record volatility

Thank you for your attention
